How to Prevent from Google Dorking:

To prevent your website from being vulnerable to Google Dorks, you can take the following steps:

- Encrypt sensitive and personal information, such as usernames, passwords, and payment details.
- Run inquiries on your website to check for any exposed sensitive data. If you find any, remove it from search results using the Google Search Console.
- Use a robots.txt file to prevent Google from indexing your website. To do this, add the following code to the robots.txt file in your root-level site directory:

User-agent: *
Disallow: /

You can also block specific directories from being crawled by Google by adding the following code to the robots.txt file:

User-agent: *
Disallow: /admin/

To restrict access to specific files, add the following code to the robots.txt file:

User-agent: *
Disallow: /privatearea/file.html

To restrict access to dynamic URLs that contain the ? symbol, add the following code to the robots.txt file:

User-agent: *
Disallow: /*?

Note: The robots.txt file is a text file that tells search engines which pages on your website they should not index. It is important to note that the robots.txt file is not a security measure, and it does not prevent anyone from accessing your website. However, it can help to prevent sensitive data from being exposed in search results.
